INTRODUCTION AND BACKGROUND

Although nursing midwifery education comprises both theory and practical, the application of theory is within the clinical environment where the students learn the art of midwifery (Ebert et al., 2016). Clinical placements are an essential educational component to undergraduate nursing and midwifery students' development as these provide an invaluable opportunity for the learners to acquire and develop skills, tacit knowledge, demonstrate conceptual understanding, and professional competency.

Acquiring of the clinical skill is a process and is an important part of nursing and midwifery education and practice. These clinical skills underpin the professional practice for nurses and midwives. These skills represent a set of knowledge and practices which aim to develop the competences necessary for the proper professional practice and these can include but not limited to; communication, psychomotor, listening etc. Becoming competent in these essential skills is mandatory for safe and effective practice (Bloomfield et al., 2008)
and learning however, poses a challenge to both the learner and the teacher as there are several factors that affect the process (Bloomfield et al., 2008; Borneuf and Haigh, 2010). High quality, supportive practice learning experiences are crucial for ensuring that student nurses and midwives become competent practitioners who have skill and are fit for practice. Norman et al. (2000) notes that the clinical learning environment facilitates or hinder the process of acquiring the professional skills.

Acquisition of skills to a level of proficiency has a number of challenges and requires more than just a clinical placement but several other factors influence learning and acquisition of skills to proficiency level during clinical placement (Felton and Royal, 2015; Lake and Hamdorf, 2004). Therefore, the process of integrating knowledge, skill and communication is a complex one. It is influenced by several factors including poor practice students observe during placement and support received including supervision.

Literature has shown that effective clinical placement require supervision and support to students to facilitate professional development (Ebert et al., 2016). The process of supervision ensures that quality nurses and midwives graduate as professionals (Laitila et al., 2007). Although there are different opinions regarding supervision of students, Tiwaken et al. (2015) noted that effective supervision by clinical teachers in clinical environment is vital for students learning.

According to Carver et al. (2014) clinical supervision is a process of supporting and learning which enables the students to develop their knowledge and competence for their own practice, and enhance client protection and safety of care in complex clinical situations. The Health Workforce Australia (2010) also defined clinical supervision as the “(oversight – either direct or indirect – by a clinical supervisor of professional procedures and/or processes performed by students)”. This therefore means that there is another individual professional who is able to direct the learner on how to learn the particular skill. With all the factors influencing students’ acquisition of skills, the question therefore is “(what role does supervision of students play during the learning process of students during clinical placement?)”

Aim of the review

The aim of the review was to determine the role of clinical Supervision in acquisition of competences among Nursing and Midwifery Students.

METHODS

Search Strategy

A search of the literature regarding supervision and acquisition of skills was undertaken using CINAHL, PubMed, Science Direct, Hinari, EBSCO Host Research, Biomed central, Cochrane Review and Google scholar databases using keywords: “clinical supervision” and “acquisition of kills” “Nursing and Midwifery Students”. The search was limited to English full-length research articles in peer-reviewed journals from the year 2005 to 2017 inclusive. The inclusion criteria considered both nursing and midwifery research articles that examined clinical supervision and or acquisition of skills in nursing and midwifery students in any type of health care setting. These studies were included in the review regardless of the methodology (qualitative and quantitative). The exclusion criteria for this literature review included any research that described clinical supervision of non-nursing and midwifery students. The reviewer also came across literature regarding supervision of clinical staff by allocated senior supervisor, however as this was not the focus but students, such articles were excluded.

RESULTS

An initial search brought out a total of 223 articles and abstracts with words related to the review topic and the search terms. These were skimmed thoroughly to determine whether they were relevant to the review topic and 25 articles were selected based on the topic of review. However, after reading through the articles only eighteen articles (Table 1) have been included in the review as they met the inclusion criteria. Despite that there is a lot of literature regarding general student supervision and different models being used, this literature search has demonstrated that there appears to be little literature that is directly relating supervision of students to acquisition of skills especially to nursing and midwifery students.

Following the review of the articles that have been included, some major concepts/themes emerged from the articles regarding the role clinical supervision plays to students learning and acquisition of skills. The following are some of the concepts/themes that emerged; Provides support and professional socialisation, Improves interpersonal and communication skills, Increases students’ opportunities and confidence in learning and Increases students’ reflective thinking, self-evaluation and decision making.

DISCUSSION

A limitation to this study is the lack of articles that are directly relating supervision to acquisition. However from the literature reviewed, it is evidently clear that acquiring clinical skill require a supportive environment for students in the clinical environment because of the complexity and challenging nature of skills acquisition (Dehghani et al., 2016; Holst and Horberg, 2013; Amsrud et al., 2015; Manninen et al., 2015; Crafoord and Fagardahl, 2016).

Despite the fact that there are other factors that have been documented to influence the process of skills acquisition, supervision has been seen to be very important (Rhodes et al., 2011; Mwale and Kalawa, 2015). Supervision has been seen to play an important role in the learning of students during clinical placement. The following discussion will focus on the identified concepts/themes.

**Provides Support and Professional Socialisation**

According the review, Clinical supervision is important in students’ learning during clinical placement. One of the findings is that clinical supervision provides a form of support which students appreciate during the learning (Franklin, 2013; Habimana et al., 2016; Mafumo et al., 2017; Brunero and Stein-Parbury, 2011). Research evidence has shown that students perform and learn better in the clinical environment if they have support from people (Elcigil and Sari, 2007). Based on the definition of clinical supervision, this support may not necessarily be from the educators but also from senior peers who

<td>Clinical supervision provides the opportunity for students and nursing educators to engage in active reflection on experiential learning experiences. Furthermore, clinical experience without appropriate clinical supervision does not assure development of essential psychiatric nursing skills. It allows student and instructor to reexamine recent experiences with actual patients and fine-tune clinical skills. Clinical supervision provides the opportunity to enhance student clinical skills based on faculty feedback regarding student performance. As clinical competencies develop, a student becomes more confident in the ability to provide clinical care. A student who sees the clinical supervision experience as beneficial is likely to seek out clinical supervision opportunities in future practice settings.</td>

</tbody>
</table>
may be more knowledgeable than them. Bourgeois et al. (2011) notes that “peer supervision and support provides students an opportunity to discuss their practice and share knowledge and skills. Lack of support has shown to be bring stress and tension among students which eventually has an effect on the student learning”

When they are given the required support, students are being able to translate their theoretical knowledge and integrate it into practice. Brunero and Stein-Parbury (2011) in their review identified the three functions according to Proctor’s model which include support and stress relief (Restorative), promoting professional accountability (Normative) and skill and knowledge development (Formative). According to Mwale and Kalawa (2016) skills acquisition can only be accomplished when there is adequate student nurses support and guidance by senior in the clinical learning environments. It is therefore this support and experiences that students receive that help them being socialized in the profession.

**Improves Interpersonal and Communication Skills**

In nursing and midwifery education and practice, interpersonal relationships and communication with patients and other members of the health care is vital (Sani et al., 2013). It is vital for both learners to learn the skills and for supervisors and practitioners to provide quality care. It enhances critical thinking and problem solving techniques. According to the reviewed articles (Amsrud et al., 2015; Dahghani et al., 2015; Lyberg et al., 2015; Russell et al., 2016), clinical supervision to students increases their awareness and improves their interpersonal, professional and communication skills which are essential to patient safety. It gives an opportunity to the students to communicate effectively with their peers and supervisors during their learning process and thereby support each other. Based on this finding, students learn these from the supervisor through communication and constructive feedback.

**Increases Student’s Opportunities and Confidence in Learning**

Another finding from the review regarding the role of supervision is skills acquisition is increasing opportunities for students to learn and therefore build their confidence to learn and practice the required skills (Holst and Horberg, 2013; Dehghan et al., 2015; Crafoord and Fagardahl, 2016; Echternacht and Young, 2008). When students are given enough opportunities during practice by their supervisors they develop confidence to try out the skills and eventually become competent in those skills. Ngaiyaye et al. (2017) in their study regarding clinical preceptors (supervisors) reported that supervisors create learning opportunities for student according to students ‘need. This facilitates the development of confidence in students. Similarly, Kristofferzon et al. (2013) as quoted by Dehghani et al. (2015) alluded to the fact that clinical supervision yields positive results during clinical education and also provided an opportunity for students to become more independent and autonomous in their learning (Carveret et al., 2014).

**Increases Student’s Reflective Thinking, Self-evaluation and Decision Making**

Reflective thinking is one of the major concepts in nursing practice. It is the ability to have a retrospective contemplation of practice undertaken in order to uncover the knowledge used in a particular situation, by analysing and interpreting the information recalled (Burns and Bulman, 2000). Literature reviewed indicates that clinical supervision is well appreciated by student as it enhances thinking and reflection on their learning as well as developing their knowledge and skills. Clinical supervision also provides an opportunity for students to engage in active reflection on previous experiences and perform self-evaluation for personal growth (Severinsson and Sand, 2010; Echternacht and Young, 2008; Manninen et al., 2015; Haggman-Laitila et al., 2007). Student nurses can become more aware of how they feel about themselves, think, and act maturely while maturely, accepting what one has to improve. While in the clinical environment students learn from real clinical experiences and their competence and decision-making skills are enhanced when they reflect together with the supervisor on critical incidents through feedback and dialogue. Evidence has shown that feedback through the reflective process helps students identify their deficiencies and this gives them confidence to work towards improving their skills (Kaphagawani and Useh, 2013).

**CONCLUSIONS**

This literature review aimed at determining role that supervision plays in acquisition of clinical skills among nursing and midwifery students. Although most of the literature does not focus directly on acquisition of clinical skills, one factor coming out in all the articles is that clinical supervision plays a vital role in the learning processes of students in the clinical area. The reviewers have also come to a conclusion that clinical supervision regardless of the model used it still has an important role when it comes to acquisition of skill by students in the clinical area. However, despite the fact that it plays an important role, other factors have to be considered during the supervision process for it to be effective; for example conductive learning environment, adequate staff and many others. Students should also have the knowledge of what clinical supervision is for them to appreciate it.
